Primary pulmonary sporotrichosis with unusual fungal morphology.

Berson SD, Brandt FA.

Primary pulmonary sporotrichosis is a rare disease.

Comstock and Wolson (1975) were able to trace approximately 30 such cases. We report a further case; to our knowledge, the various stages in the development of sporotrichosis, from a **cigar body** to the **mature asteroid body with radiations** which were present in our case, have not been so well demonstrated in a single case

**Sporothrix schenckii var Iuriei as the
cause of sporotrichosis in Italy.**

Divisione di Malattie Infettive, Ospedale
Civile, Piacenza, Italy.

The second known case of sporotrichosis caused by ***Sporothrix schenckii* var. *Iuriei*** in a patient living in Piacenza, Italy is described. In the absence of cultures, the diagnosis was based on histologic studies. Stained tissue sections (Hematoxylin and eosin, & Gomori methenamine silver) revealed hyaline, large, thick walled tissue form cells that had divided by septation or a budding process. These forms, along with the **striking "eyeglass" configuration** of incompletely separated cells that were also present, are the diagnostic features of this apparently rare variety. The use of a fluorescent antibody reagent, specific for *S. schenckii*, confirmed the identity of the etiologic agent.

Abstract

The first case of fatal pulmonary sporotrichosis caused by *Sporothrix schenckii* var. *luriei* in a patient from the northwestern region of India is described. In the absence of cultures, the diagnosis was suspected by notation, in lung tissue, of large, thick-walled, hyaline fungal cells that divided internally by septation or a budding process. The thick-walled, internally septated cells often became muriform. **The presence of an "eyeglass" configuration** of incompletely separated cells characteristic of *S. schenckii* var. *luriei* in large numbers aided the diagnosis. The identity of the etiologic agent was confirmed by application of a fluorescent-antibody reagent specific for *S. schenckii*.

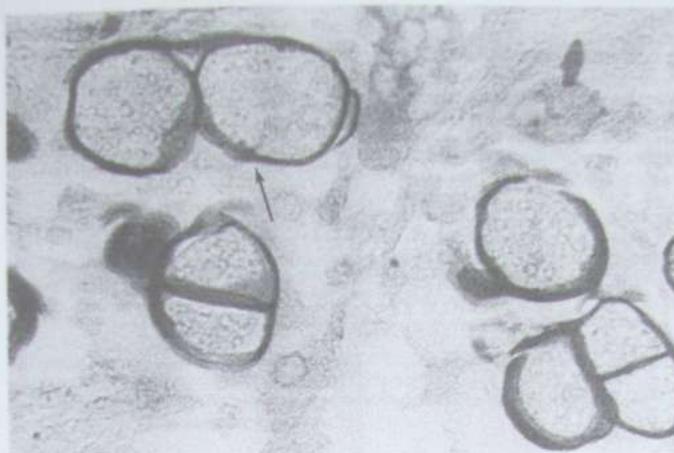

FIG. 1. Classical eyeglass-shaped form (arrow) produced by the incomplete separation of a septate cell and partial dissolution of the parental cell wall and a muriform cell of *Sporothrix schenckii* var. *luriei*, with GMS stain. Magnification, $\times 875$.

shaped appearance (Fig. 1) typical of *S. schenckii* var. *luriei*. In many cells, internal septation in different planes resulting in formation of muriform cells was also observed. Some of the larger cells were empty, being devoid of cytoplasmic contents, while some showed germ tubes (Fig. 2). A careful examination also revealed a few spherical to ellipsoidal budding cells that measured 2 to 6 μm in diameter, similar to those of *S. schenckii* var. *schenckii*. Based on the presence of thick-walled, septate cells and classical eyeglass-shaped cells (1), the possibility of the tissue form being *S. schenckii* var. *luriei* was considered.

Fluorescent-antibody staining. The deparaffinized, unstained sections were stained with a specific fluorescein-

labeled *S. schenckii* var. *schenckii* antiglobulin and examined with a Leitz Ortholux II indirect light fluorescence microscope (1, 4). Previous investigations (1, 4) revealed that this conjugate specifically stained both varieties of *S. schenckii* in vitro and *in vivo* and was nonreactive with 21 heterologous fungal species representing 12 different genera. The fluorescent-antibody reagent stained various fungal cells in the tissue sections, confirming the diagnosis of the first case of sporotrichosis in India caused by *S. schenckii* var. *luriei*. None of the fungal elements stained with control fluorescein-labeled preimmune rabbit globulin.

This report describes not only the first human pulmonary infection caused by *S. schenckii* var. *luriei* but also the first

Sporothrix luriei: a rare fungus from clinical origin.

Marimon R, Gené J, Cano J, Guarro J.

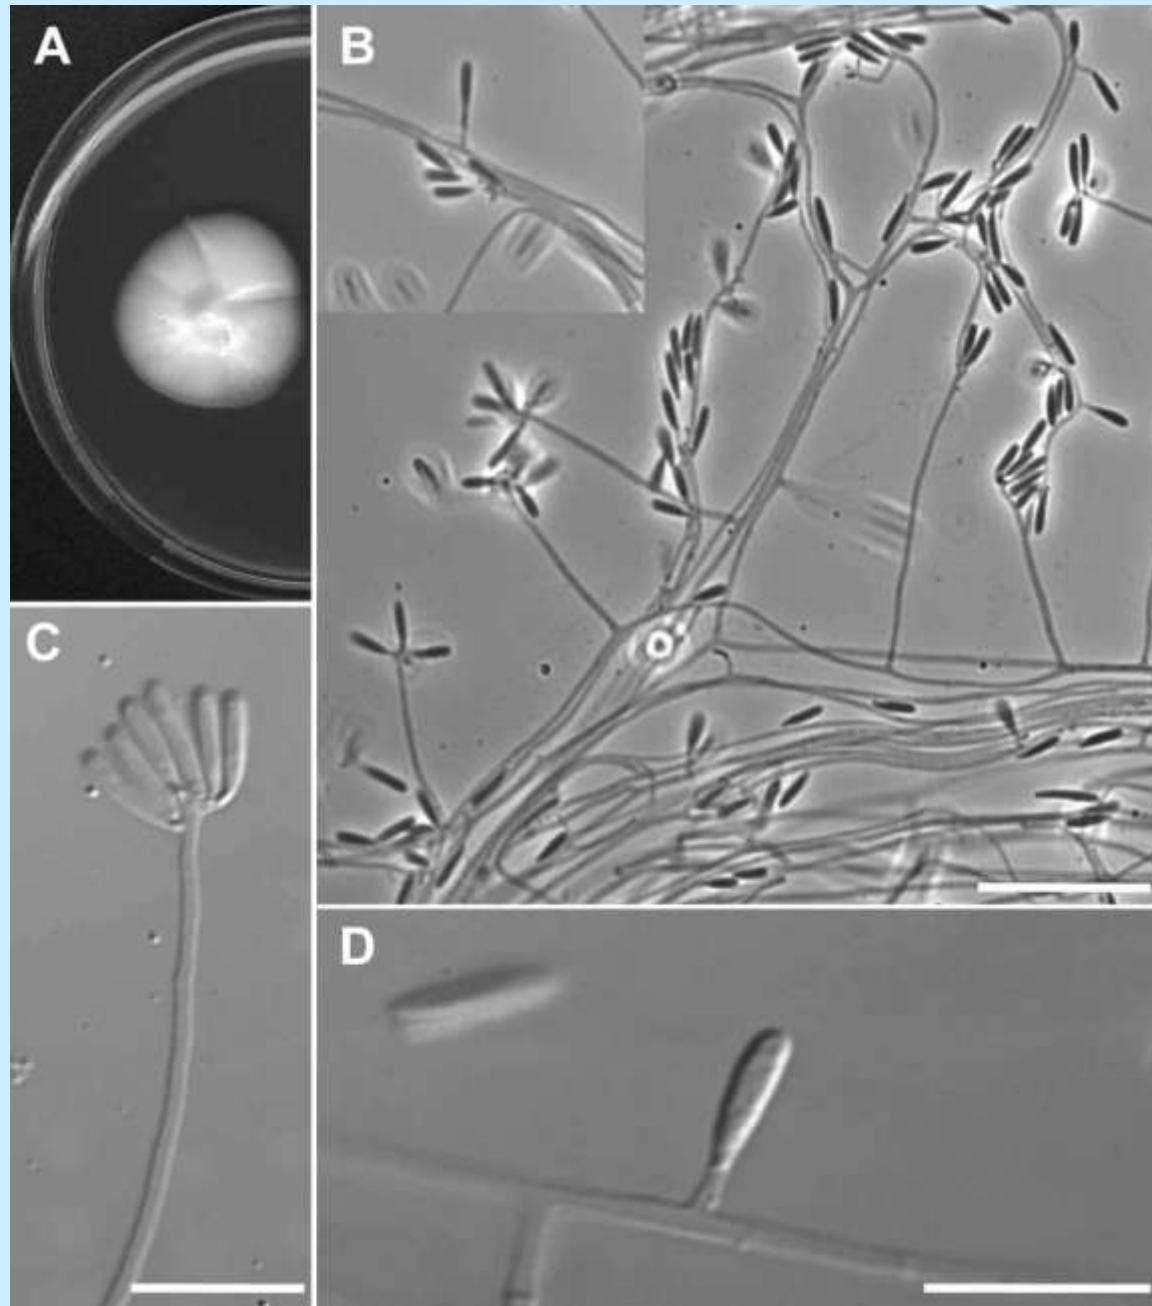

Unitat de Microbiologia, Facultat de Medicina i Ciències de la Salut, Universitat Rovira i Virgili, Reus, Spain.

Sporothrix schenckii var. luriei is a very rare pathogen reported on **four occasions from human infections**, but **only isolated from one case in Africa**. Here, it is proposed as a species different from Sporothrix schenckii on the basis of phenotypic characteristics and a multilocus sequence analysis.

Sporothrix luriei

- Se comporta como *S. brasiliensis*
- Puede afectar la casi totalidad de los órganos del cuerpo
- Su virulencia es alta
- No expresa la morfología típica (en un modelo de infección corta)
- Tratamiento de elección posaconazol
